Key words: allergic contact cheilitis; ditrimethylolpropane triethylhexanoate; lipstick; pigment solvent; synthetic branched fatty acid ester.

Lipsticks are composed of dyes, flavouring agents, sunscreens, vehicle components, and preservatives. Recently, several branched fatty acid esters have been used in lipsticks as pigment solvents in place of castor oil, because...
the latter is a known contact allergen (1). Ditrimethylolpropylene triethylhexanoate is a new branched fatty acid ester used in lipsticks. Here, we report a case of allergic contact cheilitis caused by ditrimethylolpropylene triethylhexanoate in a lipstick.

Case Report

A 38-year-old female with a history of atopic dermatitis and urticaria presented with cheilitis of several years’ duration. She had been treated with topical steroids, and changed her lipstick a year ago, but her cheilitis had not improved. Patch tests were performed with the Japanese standard allergens as well as samples of her cosmetics, applied on her back with Finn Chambers® on Scanpor® tape (Epitest Ltd, Tuusula, Finland). The tests were occluded for 2 days, and read according to the International Contact Dermatitis Research Group Scoring Scale (2) on D2, D3, and D7. There was a positive reaction to her current lipstick ‘as is’. The patient was subsequently patch tested according to the list of 18 ingredients in the lipstick obtained from the manufacturer. The ingredients were prepared in pet., and the patient showed a positive reaction to ditrimethylolpropylene triethylhexanoate ‘as is’ (Table 1). Ditrimethylolpropylene triethylhexanoate accounted for 15% of the lipstick. A total of four consecutive controls were negative to ditrimethylolpropylene triethylhexanoate ‘as is’. From these observations, we diagnosed the patient as having allergic contact cheilitis caused by ditrimethylolpropylene triethylhexanoate in the lipstick.

Discussion

There are reports of allergic contact dermatitis caused by lipsticks (1, 3–6). Cases of allergic contact cheilitis caused by isopalmityl diglyceryl sebacate (3, 6), glyceryl isostearate, and diisostearyl malate (7) – chemicals used in place of castor oil in lipsticks – have been reported. Ditrimethylolpropylene triethylhexanoate was first introduced onto the market in 2003. Ditrimethylolpropylene triethylhexanoate is a new pigment solvent that has superior pigment dispersibility to conventional solvents such as diisostearyl maleate (8). It is a white or light yellow liquid oil, and is a triester consisting of ditrimethylolpropylene and 2-ethylhexanoate (8) (Fig. 1). When ditrimethylolpropylene triethylhexanoate is used together with wax, the mixture is hard, and this enables the lipstick to have a smoother texture because of the reduction in the volume of wax in the lipstick (8). Ditrimethylolpropylene triethylhexanoate is stable against heat, and mixes well with other oils; it may be used for various products, such as skin care products (8). Our case demonstrates that ditrimethylolpropylene triethylhexanoate has sensitizing properties. This is the first case of allergic contact dermatitis caused by ditrimethylolpropylene triethylhexanoate reported in the literature.
